

ABSTRACT

This application is designed for the use of CAB BOOKING System and its functioning Main Objective of this project to facilitate the transactions through use of electronic medium. We use java NetBeans and MySQL to program our project. This project mainly deals with creating a java application regarding cab booking. For this application we will store some car model names, their registration number, rent rate on the basis of per day, and the amount to be deposited accordingly. Cab booking system provides reliable online cab(car) booking facility to people in various locations in India, free of cost. Bumpacars acts like a bridge between the cab operators and the users who book a cab. This is the online cab booking service provided to customers. This brings together the registered cab owners and the customers.

AIM

The purpose of this document is to specify the cab booking functionality. This kind of development is now present in most of the developing cities. It would be user friendly and makes people on the easier side for transportation in large cities. This would change the traditional system and helpful in time management of the workload in the modern-day livelihood. Here the customers can book a cab /taxi/car by viewing all the cab details and pricing details available, according to selected city and area. It is the reliable service provided to both customers and drivers. This provides service with well-conditioned new vehicles, with experienced drivers for a happy journey of the customers.

Algorithm

1. START
2. Create a database on MySQL and use the database[use <database_name>;]
3. Create tables for storing and retrieving the login data, for retrieving the driver details and for retrieving the distances between the locations.
4. Create the JFrames for a user WELCOME message and provide the mouseclicked event handler.
5. Create JFrame for Login and sign up details to be retrieved from the user.
6. Initialise the MySQL server and connect the JFrames(Login and Sign Up) with the database and tables for storing and retrieving the details. On Login the details are fetched from the logininfo table created in the bumpacars database. For Sign up, the values fetched from all the text fields are stored into a logininfo table into respective columns(also called attributes).
7. Create a JFrame to input pick-up location, drop location and to select the car model.
8. Create a JFrame to redirect the user to a confirmation page that shows driver name, fare, car number and a picture of the route map.
9. Provide the connection for the gmail smtp to connect with the internet and the email address of the user retrieved from the logininfo table(from the MySQL).
- 10.Create a confirmation JFrame to appear on sending the mail to the user.
- 11.END

JAVA MAIL API

The JavaMail API provides a platform-independent and protocol-independent framework to build mail and messaging applications. The JavaMail API provides a set of abstract classes defining objects that comprise a mail system. It is an optional package (standard extension) for reading, composing, and sending electronic messages.

Following are some of the protocols supported in JavaMail API:

- **SMTP**: Acronym for **Simple Mail Transfer Protocol**. It provides a mechanism to deliver email.
- **POP**: Acronym for **Post Office Protocol**. POP is the mechanism most people on the Internet use to get their mail. It defines support for a single mailbox for each user. RFC 1939 defines this protocol.
- **IMAP**: Acronym for **Internet Message Access Protocol**. It is an advanced protocol for receiving messages. It provides support for multiple mailbox for each user, in addition to, mailbox can be shared by multiple users. It is defined in RFC 2060.
- **MIME** : Acronym for **Multipurpose Inter net Mail Extensions**. .It is not a mail transfer protocol. Instead, it defines the content of what is transferred: the format of the messages, attachments, and so on. NNTP and Others:There are many protocols that are provided by third-party providers. Some of them are Network News Transfer Protocol (NNTP), Secure Multipurpose Internet Mail Extensions (S/MIME) etc.

JAVA

Java is a general purpose object oriented programming language . It is the first programming language that is not tied to any particular hardware or operating system. The language is based on the concept of an object. Java is highly derived from C++. Most striking feature of the language is that it is platform neutral language.

There were five primary goals in the creation of the Java language:

- It should use the object-oriented programming methodology.
- It should allow the same program to be executed on multiple operating systems.
- It should contain built-in support for using computer networks.
- It should be designed to execute code from remote sources securely.
- It should be easy to use and borrow the good parts of older object-oriented languages like C++.

MySQL

SQL is not a procedural language. It is not used to define complex processes; we can use SQL to use commands that define and manipulate data. SQL is different from other languages.

- SQL is very readable.
- In SQL we always issue commands.

SQL statements fall into two groups:-

- Data Definition Language (DDL) – DDL statements are used to describe the tables and the data they contain. The subset of SQL statements used for modeling the structure (rather than the contents) of a database or cube. The DDL gives you the ability to create, modify, and remove databases and database objects.
- Data Manipulation Language (DML) – DML statements that are used to operate on data in the database. These are statements that allow you to create or alter objects (such as tables, indexes, views, and so on) in the database. The subset of SQL statements used to retrieve and manipulate data.

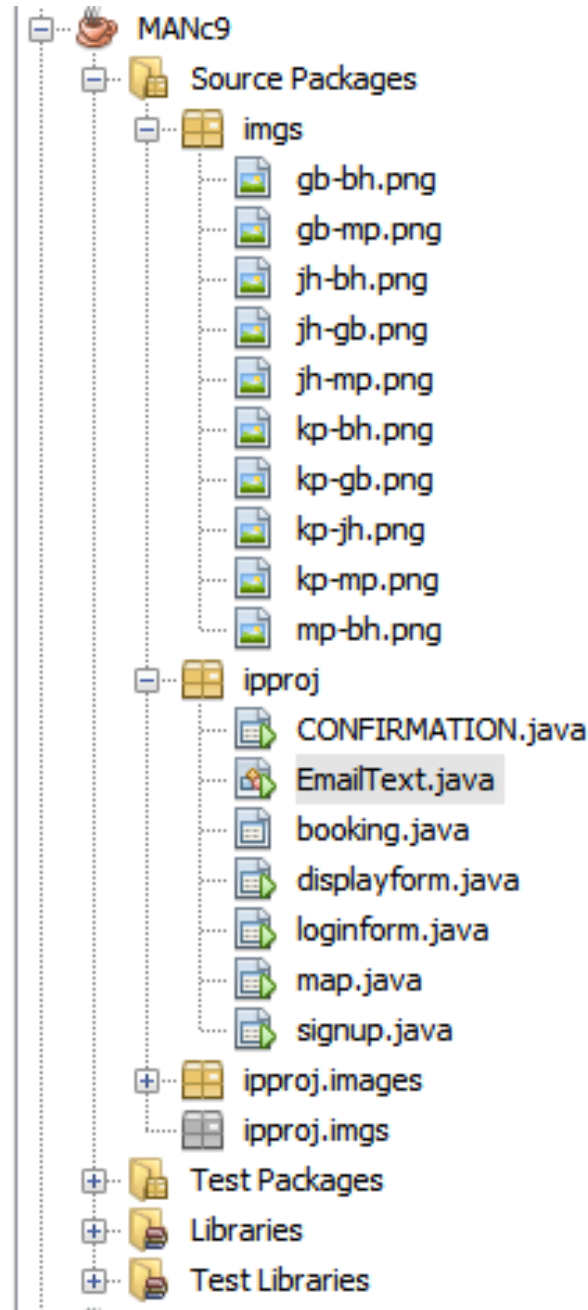

NetBeans

NetBeans IDE is a free, open source, integrated development environment (IDE) that enables you to develop desktop, mobile and web applications. The IDE supports application development in various languages, including Java, HTML5, PHP and C++. The IDE provides integrated support for the complete development cycle, from project creation through debugging, profiling and deployment. The IDE runs on Windows, Linux, Mac OS X, and other UNIX-based systems. The IDE provides comprehensive support for JDK 8 technologies and the most recent Java enhancements. It is the first IDE that provides support for JDK 8, Java EE 7, and JavaFX 2.

NetBeans
